Executive Summary

This report outlines the development process and technical competencies acquired during the SAP Build Apps introductory course. The project focuses on the rapid creation of a Customer and Sales Order Management application, utilizing Generative AI and low-code methodologies within the SAP Business Technology Platform (BTP) ecosystem.

Project Foundation and Data Integration

The development begins with the establishment of a project framework integrated directly with SAP BTP. A critical component of this phase was the configuration of data resources, where a specific SAP S/4HANA destination was selected to serve as the application's backbone. By establishing this connection, the application can perform live data operations, ensuring that all sales order information remains synchronized with the enterprise's core system.

AI-Driven Interface Generation

A primary focus of the training involved leveraging Generative AI to accelerate the UI/UX design phase. Rather than manual component placement, AI can generate complex functional pages, such as the Sales Order listing, creation forms, and detailed read-only views. This approach demonstrates a significant shift in enterprise development, where the AI interprets data structures to build relevant user interfaces super fast.

Logic Configuration and UI Optimization

Following the initial generation, the application was refined through the SAP Build logic canvas. The technical workflow involved configuring the Get Record Collection properties to implement professional data handling features such as custom ordering, filtering, and paging. To ensure a streamlined user experience, AI-generated pages were "cleaned" by removing redundant data fields such as delete or add button, resulting in a focused interface tailored to specific business requirements.

Validation and Deployment

Lastly, the project involved rigorous testing through the application's preview mode. This stage confirmed the successful end-to-end flow of data, from the initial trigger of a workflow to the successful population of dropdown with S/4HANA material data. The process concluded with a deployment-ready application capable of creating and viewing real-time sale orders, proving the efficiency of SAP's low-code environment for modern business needs.
